Exp No:11

Deploying a Zoho Creator Application from Development to Production Environment

Aim

To deploy a Zoho Creator application from the development environment to the production environment and verify its functionality, data integrity and accessibility.

Record Status

Completed after deploying and testing the application in the production environment.

Concept

Deployment is the process of moving an application from a development environment to a production environment where end users can access and use it.

Zoho Creator supports application publishing and deployment through its available development, publishing, and environment management features. Before deployment, the application must be tested to ensure that its forms, reports, workflows, Deluge scripts, permissions and integrations work correctly.

Procedure

1. Log in to Zoho Creator and open the Loan Application Management System.
2. Review the application forms, reports, dashboards, workflows, and Deluge scripts.
3. Test the application in the development environment using sample records.
4. Verify that all required fields, validation rules, and workflow actions function correctly.
5. Review user permissions and access restrictions.
6. Identify the deployment or publishing options available for the application.
7. Use the appropriate Zoho Creator deployment or publishing procedure to move the tested changes to the target environment.
8. Configure any required connections, permissions, and environment-specific settings.
9. Open the published application and test its main functions.
10. Verify that users can access only the forms, reports and records permitted by their roles.

Application Design

The Loan Application Management System contains the following components:

- Forms: Collect applicant details and loan information.
- Reports: Display and manage submitted loan applications.

- Dashboard: Summarizes application status and processing information.
- Workflows: Automate application validation and status updates.
- Deluge scripts: Perform calculations and business logic.
- User permissions: Control access to sensitive applicant information.

These components must be checked during deployment to ensure that the application operates correctly in the target environment.

Observations

1. Testing before deployment helps identify errors early.
2. Publishing makes the application available to authorized users.
3. Correct permissions protect confidential applicant information.
4. Workflows and scripts must be verified after deployment.
5. Environment-specific connections and configurations may require additional setup.

Validation and Discussion

After deployment, test the application by submitting a sample loan application, checking the calculated values, verifying status updates, and opening the relevant reports and dashboards.

Confirm that required fields, validation rules, workflows, and role-based permissions work as expected. Verify that no unintended access to confidential applicant data is possible.

The exact deployment process depends on the Zoho Creator plan and the deployment or environment-management features available in the account.

Result

Thus, the procedure for deploying a Zoho Creator application from the development environment to the production environment was studied, and the application was validated to ensure its functionality, accessibility, and security.
